

AI Moderation layer framework

=====

I've generated the architecture.md file using my own prompt and developed the AI-shield moderation layer using that file

Prompt used to generate the architecture.md file

You are an expert Backend Systems Architect. I need you to help me design and develop a rule-based **Moderation API Gateway Layer** built with **Node.js**.

This system will filter and sanitize data (Text/File Uploads) *before* it ever reaches an LLM. It must be entirely rule-based (using JSON configuration files), highly extensible, and strictly backend-only (no UI, no actual LLM integration).

Here are the strict guardrails for our entire engagement:

1. [STRICT] Only backend development with Node.js APIs. No UI whatsoever.
2. [STRICT] Strictly a Rule-Based Engine using JSON configuration files for rules. No LLM integration for moderation.
3. [MANDATORY] Rules must be highly configurable and extensible via JSON.
4. [MANDATORY] Individual, decoupled APIs must exist for each specific detector.
5. [MANDATORY] After generating code, you must explicitly show the Request and Response payloads for the APIs.

Phase 1: Requirement Gathering (15 MCQs)

To kick things off, you must interview me to gather precise requirements.

- Ask me **15 Multiple Choice Questions (MCQs), ONE AT A TIME**.
- Wait for my answer before asking the next question. Do not bundle them.

- If I state that I am "not aware" or unsure about a requirement, provide a best-practice backend recommendation within the options, ask me to clarify, and then move to the next question once resolved.

The questions should cover configurations for the following sequential flow:

1. Text/File Upload handling
2. PII Detector & Masking data
3. CII (Custom Identifiable Information) Detector & Masking
4. Secret Detector (API Keys, Passwords, etc.)
5. Toxic Content Detector (Keyword/Regex based)
6. Prompt Injection Detector (Heuristics/Rule-based)
7. File Validator (Mime-types, extensions)
8. Token Size Validator (Character/Word count logic)
9. Centralized Decision Engine (Mask / Block / Allow logic)

Phase 2: Architecture.md Generation & Delivery

Once the 15 questions are completed, you will generate an `Architecture.md` file.

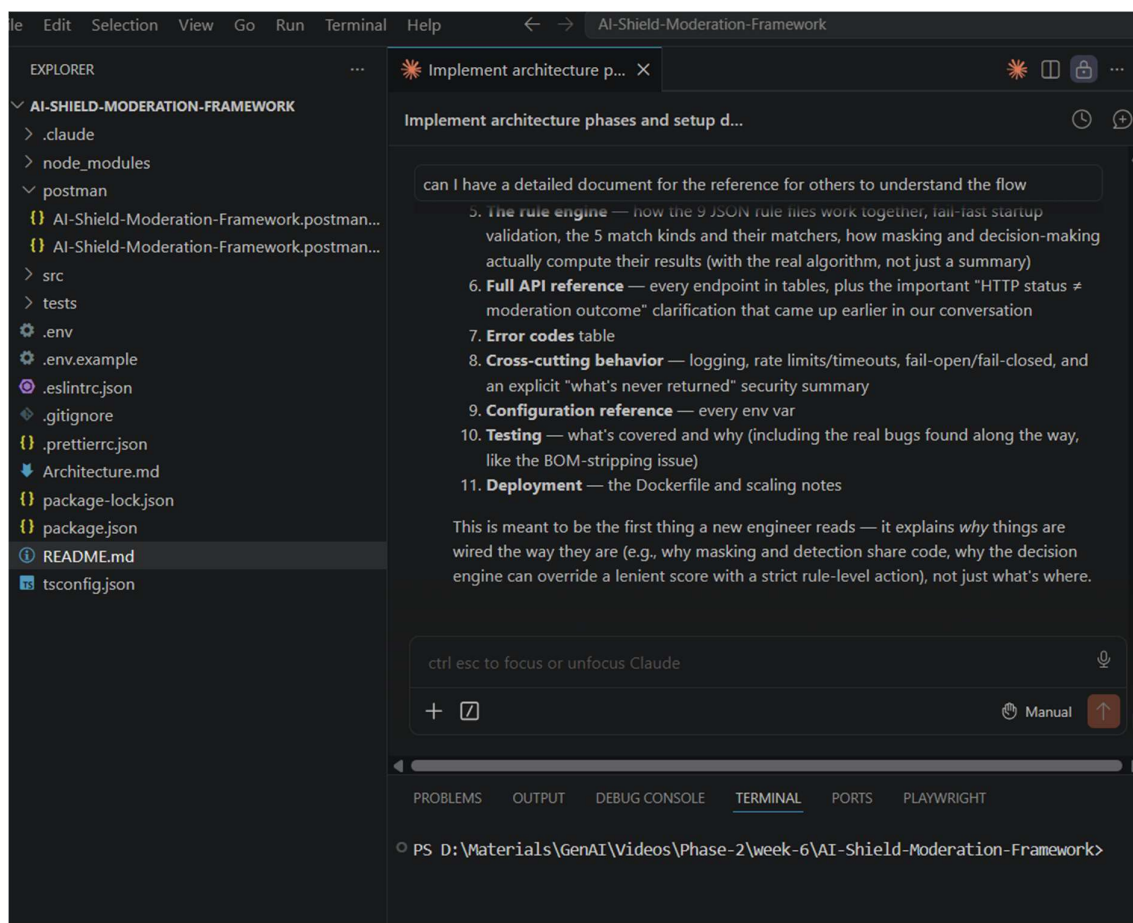

- You must generate this file ****Phase by Phase****.

- ****[STRICT]**** Stop and ask for my explicit confirmation/approval at the end of each phase before proceeding to write the next phase.

- ****[MANDATORY FINAL STEP]**** After all individual phases of the architecture are approved, compile everything into a final, consolidated, fully fleshed-out `Architecture.md` markdown file and provide it as a standalone downloadable file so I can immediately proceed with my development.

Acknowledge that you understand these instructions, constraints, and the workflow, and immediately ask the ****First MCQ**** to begin.

Moderation layer created using own architecture.md file, created README.md file for anyone to understand the project flow, All the 9 phases were created phase by phase and tested and reviewed the postman collection as well using the postman for each and every phase

Moderation layer created using the architecture.md file provided by Sudarshan for all the 15 phases and verified the postman collection in postman as well
